# DOCUMENT 7

# FLOW AUTOMATION GUIDE - PLATFORM SUPPORT

## Platform Support Workflow Design

The Platform Support Workflow is specifically engineered to resolve technical glitches with high velocity. At ABC Corporation, the 'Platform' team is responsible for managing critical issues such as login failures and server-side errors. The primary objective of this workflow is to identify multiple technical issue types through a single automated flow and route them accurately to the 'Platform' assignment group.

## Flow Creation - 'Regarding Platform'

Steps to initiate the new flow:

1. Flow Designer: Access the Flow Designer module by searching for it in the Filter Navigator.
2. New Flow: Click on the 'New' button and name the flow "Regarding Platform".
3. Properties:
    - Description: Automation for Platform-related issues including Login failures, 404 Errors, and User Expiry.
    - Run as: Select 'System User' to ensure consistent execution regardless of the triggering user's permissions.
4. Submit: Click submit to open the flow configuration canvas.

**Trigger Setup - Monitoring 'Operations related' Table**

The trigger logic for this flow is as follows:

- Trigger Type: Record Created or Updated.
- Table Name: u_operations_related.
- Strategy: Whenever a change occurs in this table, the system immediately evaluates the 'Issue' field. This ensures real-time monitoring and near-instantaneous ticket routing.

**Multiple Condition Logic (OR Condition) - Part 1**

The Platform support flow is more complex than the Certificate support flow as it utilizes 'OR' logic:

- Concept: Since multiple issue types (Login, 404, Expiry) fall under the same team's expertise, they are grouped into one flow.
- New Criteria: For each distinct problem type, a 'New Criteria' (OR condition) is added to the trigger.

**Multiple Condition Logic (OR Condition) - Part 2**

Condition Building Steps:

1. First Condition: Field: Issue | Operator: is | Value: Unable to login to platform.
2. Add New Criteria: Clicking this creates the 'OR' relationship.
3. Benefit: This architecture allows the flow to trigger if any of the specified issues occur, preventing the need for multiple redundant flows and optimizing system performance.

**Condition 1 - 'Unable to login to platform'**

Primary Technical Issue:

- Field: Issue.
- Value: Unable to login to platform.
- Technicality: Login issues are categorized as high-priority disruptions. This condition ensures such critical tickets reach the Platform team without human intervention.

**Condition 2 - '404 Error'**

Secondary Technical Issue:

- Field: Issue.
- Value: 404 Error.
- Context: This error typically indicates application downtime or broken internal links. Only the Platform team has the backend access required to investigate and resolve these infrastructure-level errors.

**Condition 3 - 'Regarding User expired'**

Tertiary Technical Issue:

- Field: Issue.
- Value: Regarding User expired.
- Logic: When a user's account reaches its expiration date, the ticket is routed to the Platform team to handle account reactivation and credential resets.

**Action Configuration - Assignment to 'Platform' Group**

Action to be executed upon matching conditions:

1. Add Action: Select the 'Update Record' action from the ServiceNow Core category.
2. Field Mapping: Choose the 'Assigned to group' field.
3. Set Value: Select the Platform assignment group.
4. Data Pill: Drag the 'Operations related' record from the data pill picker into the 'Record' field to ensure the correct ticket is updated.

**Testing Complex Scenarios**

Due to the multiple conditions, rigorous testing is required:

- Scenario A: Test with a record where Issue is '404 Error'. Verify if it routes to the Platform group.
- Scenario B: Test with a record where Issue is 'Regarding Certificates'. Verify if the flow correctly skips execution.
- Result: These tests confirm the reliability and precision of the automated logic.

**Performance Monitoring of Flows**

Utilizing the 'Execution' tab in Flow Designer:

1. Flow State: Verify that the state shows as 'Completed' for processed tickets.
2. Runtime: Monitor the execution time (should ideally be in milliseconds) to ensure no system lag.
3. Audit: Cross-reference the table history to confirm that the 'Assigned to group' change was performed by the system flow.

**Project Conclusion - Efficiency Impact Analysis**

Summary of the ABC Corporation Automation Initiative:

- Manual Effort: 0% manual intervention in ticket assignment.
- Speed: Ticket routing time reduced from an average of 5 minutes to under 2 seconds.
- Resource Optimization: Team managers like Katherine and Niranjan can now focus on high-level resolution tasks instead of administrative routing.
- Future-Proofing: This framework is scalable, allowing more teams and issue types to be added to the automation engine as the company grows.
